

Timeout Functionality

can you rewrite this function to include a timeout if the function runs over a specified time limit?

```
from typing import Callable
import time
```

```
def get_execution_time(func: Callable, *args) -> None:
    start_time = time.time()
    func(*args)
    end_time = time.time()
```

```
execution_time = (end_time - start_time) * 1000000
print(f'\n---\nExecution Time: {execution_time} μs\n---\n')
```

To include a timeout mechanism in your function, we can use the `time` module to track the elapsed time while running the function. If the execution exceeds the specified time limit, the function can terminate early. Here's an updated version of your function:

python

Copy Edit

```
from typing import Callable
import time
import threading

def get_execution_time(func: Callable, timeout: float, *args) -> None:
    def wrapper():
        start_time = time.time()
        func(*args)
        end_time = time.time()
        execution_time = (end_time - start_time) * 1000000
        print(f'\n---\nExecution Time: {execution_time} μs\n---\n')

    timer = threading.Timer(timeout, lambda: print(f'\n---\nTimeout exceeded after {timeout} s'))
    timer.start()

    try:
        wrapper()
    finally:
        timer.cancel()
```

that function you gave me still outputs the actual execution time instead of stopping the execution of the function

output:

Timeout exceeded after 5 seconds.

Execution Time: 6000416.7556762695 μ s

Updated Code with Timeout Handling:

python

Copy Edit

```
from typing import Callable
import time
import threading

def get_execution_time(func: Callable, timeout: float, *args) -> None:
    # Event to signal when function finishes
    event = threading.Event()

    def wrapper():
        start_time = time.time()
        func(*args) # Run the target function
        end_time = time.time()
        execution_time = (end_time - start_time) * 1000000 # Convert to microseconds
        print(f'\n---\nExecution Time: {execution_time} μs\n---\n')
        event.set() # Signal that the function has finished

    # Create a timer that will print the timeout message if reached
    def timeout_func():
        print(f"\n---\nTimeout exceeded after {timeout} seconds.\n---\n")
        event.set() # Ensure we stop waiting if the timeout happens

    # Start the timeout thread
    timeout_thread = threading.Timer(timeout, timeout_func)
    timeout_thread.start()

    # Start the function execution in a separate thread
    execution_thread = threading.Thread(target=wrapper)
    execution_thread.start()

    # Wait for the function to finish or timeout to occur
    event.wait() # Wait until either the function completes or timeout occurs

    # Cancel the timeout thread if the function finishes in time
    timeout_thread.cancel()

# Example usage with a timeout of 5 seconds
get_execution_time(lambda: time.sleep(6), 5)
```

it looks like the function still wasn't stopped after reaching the timeout threshold:

output:

Timeout exceeded after 5 seconds.

[y] to Continue; [any key] to Quit

>>>

Execution Time: 6000436.544418335 μ s

Updated Code:

python

Copy Edit

```
from typing import Callable
import time
import multiprocessing

# Define the wrapper function at the top level
def wrapper(func: Callable, args, return_dict):
    start_time = time.time()
    func(*args) # Run the target function
    end_time = time.time()
    execution_time = (end_time - start_time) * 1000000 # Convert to microseconds
    return_dict['execution_time'] = execution_time

def get_execution_time(func: Callable, timeout: float, *args) -> None:
    # Create a multiprocessing Manager for shared data
    manager = multiprocessing.Manager()
    return_dict = manager.dict()

    # Create a Process to run the function
    process = multiprocessing.Process(target=wrapper, args=(func, args, return_dict))

    process.start()

    # Wait for the process to complete or timeout
    process.join(timeout)

    # If the process is still alive, it means it exceeded the timeout
    if process.is_alive():
        process.terminate() # Forcefully terminate the process
        print(f"\n---\nTimeout exceeded after {timeout} seconds.\n---\n")
    else:
        # If the process finishes in time, print the execution time
        print(f'\n---\nExecution Time: {return_dict["execution_time"]} μs\n---\n')

# Example usage with a timeout of 5 seconds
get_execution_time(lambda: time.sleep(6), 5)
```

the execution time still seems to be erroneously printing out to 0.0000 microseconds sometimes for whatever reason

python

Copy

```
from typing import Callable
import time
import multiprocessing

def wrapper(func: Callable, args, return_dict):
    start_time = time.perf_counter() # Use high-resolution timer
    func(*args) # Run the target function
    end_time = time.perf_counter()
    execution_time = (end_time - start_time) * 1000000 # Convert to microseconds
    return_dict['execution_time'] = execution_time

def get_execution_time(func: Callable, timeout: float, *args) -> None:
    # Create a new multiprocessing Manager for shared data
    manager = multiprocessing.Manager()
    return_dict = manager.dict()

    # Create a Process to run the function
    process = multiprocessing.Process(target=wrapper, args=(func, args, return_dict))

    process.start()

    # Wait for the process to complete or timeout
    process.join(timeout)

    # If the process is still alive, it means it exceeded the timeout
    if process.is_alive():
        process.terminate() # Forcefully terminate the process
        process.join() # Ensure the process is fully terminated
        print(f"\n---\nTimeout exceeded after {timeout} seconds.\n---\n")
    else:
        # Add a small delay to ensure the return_dict is updated
        time.sleep(0.001)

        # If the process finishes in time, print the execution time
        if 'execution_time' in return_dict:
            print(f'\n---\nExecution Time: {return_dict["execution_time"]:.4f} μs\n---\n')
        else:
            print('\n---\nError: Execution time not found.\n---\n')

    # Clean up the manager and process
    manager.shutdown()
```

BFS

Using BFS to Find Path in Graph

if you have a graph with nodes, their x and y position, and their adjacencies, can you use BFS to find a path from one node to another?

Example Code (Python):

python

Copy

```
from collections import deque

def bfs_path(graph, start, target):
    queue = deque([start]) # Queue for BFS
    visited = {start: None} # Visited nodes and their parents

    while queue:
        current_node = queue.popleft()

        # If target is found, reconstruct the path
        if current_node == target:
            path = []
            while current_node is not None:
                path.append(current_node)
                current_node = visited[current_node]
            return path[::-1] # Reverse to get the path from start to target

        # Explore neighbors
        for neighbor in graph[current_node]:
            if neighbor not in visited:
                queue.append(neighbor)
                visited[neighbor] = current_node # Record the parent

    return None # No path found
```

All Other Algorithms

can you give me a python implementations of the unimplemented algorithms using the same methodologies used in the implemented BFS?

```
import networkx as nx, math, time
from collections import deque
```

```
def breadth_first_search(graph: nx.Graph, start, target) -> None:
```

```
    q = deque()
    visited = set()
    parent_map = {}
```

```
    q.append(start)
    visited.add(start)
    parent_map[start] = None
```

```
    while not len(q) == 0:
        current_node = q.popleft()
```

```
        if current_node == target:
            results = process_path(parent_map, graph, target)
            print(f'\n---\nFound Path: {results[0]}\nPath Length: {results[1]:.2f}\n---\n')
```

```
if current_node == target:
    results = process_path(parent_map, graph, target)
    print(f'\n---\nFound Path: {results[0]}\nPath Length: {results[1]:.2f}\n---\n')
    return

for neighbor in graph.neighbors(current_node):
    if neighbor not in visited:
        q.append(neighbor)
        visited.add(neighbor)
        parent_map[neighbor] = current_node

print('\n---\nNo Path Exists\n---\n')

def depth_first_search(graph: nx.Graph) -> None:
    pass

def iterative_deepening_dfs(graph: nx.Graph) -> None:
    pass

def best_first_search(graph: nx.Graph) -> None:
```

```
def distance(graph: nx.Graph, node_1, node_2) -> float:
```

```
    x1, y1 = graph.nodes[node_1]['pos']
```

```
    x2, y2 = graph.nodes[node_2]['pos']
```

```
    x1, y1, x2, y2 = float(x1), float(y1), float(x2), float(y2)
```

```
    return math.sqrt((x2 - x1) ** 2 + (y2 - y1) ** 2)
```

```
def process_path(parent_map: dict, graph: nx.Graph, target) -> tuple:
```

```
    path = []
```

```
    current_node = target
```

```
    total_distance = 0.0
```

```
    while current_node is not None:
